

Provincialism in Gondwana floras

Hari K. Maheshwari

Maheshwari HK 1992. Provincialism in Gondwana floras. *Palaeobotanist* 40 : 101-127.

The Gondwana sediments of India, ranging from Asselian to Rhaetian in age, contain remnants of a unique flora that in general composition is uniform all over. Two basic floral assemblages, i.e., *Glossopteris*-Assemblage and *Dicroidium*-Assemblage, can be recognized through Permian and Triassic, respectively. A synthesis of data on distribution of plant fossils in different formations of the Gondwana Supergroup brings out an incipient provincialism throughout, particularly in the Barakar Formation. It is not yet understood if this provincialism is apparent or real.

Key-words—Gondwana Supergroup, *Glossopteris* Flora, *Dicroidium* Flora, Provincialism, Biostratigraphy, Phyogeography, India.

Hari K. Maheshwari, Birbal Sahni Institute of Palaeobotany, 53 University Road, G.P.O. Box 106, Lucknow 226 001, India.

सारोंश

गोंडवाना वनस्पतिजातों में प्रान्तीयता

हरिकृष्ण माहेश्वरी

अंसेलियन से रिहैटियन आयु के भारतीय गोंडवाना अवसादों में एक विशेष वनस्पतिजात के पादप-अवशेष मिलते हैं जो कि संरचना की द्रविट से एक जैसे हैं। क्रमशः परमी एवं त्रिसंधी कल्पों में वस्तुतः दो वनस्पतिजातीय समुच्चय—ग्लॉबॉन्टोप्टेरिस समुच्चय एवं डाइक्रोइडियम समुच्चय, अभिनिधारित किये जा सकते हैं। गोंडवाना महासमूह के विभिन्न शैल-समूहों में अश्विमत पौधों के वितरण से सम्बद्ध औंकड़ों के संश्लेषण से प्रान्तीयता की स्पष्ट झलक मिलती है विशेषतया बराकर शैल-समूह में। अभी तक यह स्पष्ट नहीं हो पाया है कि यह प्रान्तीयता वास्तविक है अथवा आभासी।

THE term Gondwana floras relates to the succession of remnants of a vegetation that have been recorded from the Gondwana sediments of India. The unit Gondwana was originally proposed for a group of sediments laid down in a primarily fresh-water environment (Medlicott, 1872—unpublished). In subsequent years three distinct floral associations were recorded from the Gondwana group of sediments, within a time slice of Late Carboniferous to Early Cretaceous (see Lele, 1976). The composition of the contained floras led to the inclusion of certain coastal marine sedimentaries of Cretaceous age, and also a group of sediments of Early Permian age from western Himalayan region within the purview of the Gondwana. The concepts, limits and extension of the Indian Gondwana have been debated in recent years. One of the proposals fixes the status of the Gondwana as a supergroup comprising an almost continuous sequence of essentially terrigenous sediments, the deposition of

which was preceded and followed by large hiatuses. The time slot of the Gondwana Supergroup in India has now been fixed between earliest Permian and latest Triassic (Venkatachala & Maheshwari, 1991). The Gondwana sediments were deposited in the three major grabens, viz., Damodar, Son-Mahanadi and Pranhita-Godavari, besides several smaller basins.

The Gondwana Supergroup in the Damodar Graben is classified as follows:

| | hiatus | |
|----------------|----------------|---|
| Mahadeva Group | T ₃ | Supra Panchet |
| Panchet Group | T ₂ | Formation ¹ |
| | T ₁ | { Hirapur Formation ² Maitur Formation ³ |

| | | |
|---------------|----------------|---------------------------------|
| Damuda Group | P ₂ | Raniganj Formation ⁴ |
| Talchir Group | P ₁ | Kulti Formation ⁵ |
| | P ₁ | Barakar Formation ⁶ |
| | hiatus | Talchir Formation |

- 1) Equivalent formations—Dubrajpur (Rajmahal Basin), Tiki and Parsora (Son Graben), Pachmarhi and Denwa (Satpura Graben), and Dharmaram, Maleri and Bheemaram (Pranhita-Godavari Graben).
- 2) Equivalent to top of 'Kamthi' (Godavari Graben).
- 3) Equivalent to Upper 'Kamthi' (Godavari Graben) and Upper Hinjir (Mahanadi Graben).
- 4) Equivalent formations—Pachwara (Rajmahal Basin), Pali (Son Graben), Hinjir (Mahanadi Graben), Kamthi (Wardha Coalfield), Bijori (Satpura Graben).
- 5) Also known as Barren Measures (Damodar Graben) or Motur (Satpura Graben). May also include basal part of the 'Kamthi' (Godavari Graben).
- 6) Basal part sometimes known as Karharbari 'Formation'. Equivalent formations are Nishatbagh and Mamal (Kashmir Valley, Pir Panjal and Parauthochrone), Khelong/Rilu (eastern Himalaya).

After the initial report of plant fossils from the Raniganj Coalfield (Brongniart, 1828), mega- and micro-fossils have been reported from almost all the horizons (see Lakhanpal, Maheshwari & Awasthi, 1976; Chandra & Singh, 1989; Maheshwari, Singh & Bajpai, 1989; Bajpai, 1990; Bajpai & Tewari, 1990; Chandra, Srivastava & Singh, 1990; Prasad & Maithy, 1990; Singh & Bajpai, 1990; Singh & Chandra, 1990; Bajpai & Maheshwari, 1991; Chandra & Tewari, 1991; Srivastava, 1991; Kapoor, Bajpai & Maheshwari, 1992; Maheshwari & Bajpai, 1992, etc.).

Table 1 lists plant megafossils known so far from different formations of the Gondwana Supergroup. Tables 2-15 list plant megafossils for each important formation and show their areal distribution.

In recent years a few papers have analysed the palaeobotanical implications or rather palaeobotanical evidences on the northern limits of the Indian Plate during the Gondwana period. Use of palaeobotanical data for phytogeographic considerations one can understand. But to demarcate plate boundaries on the basis of elements of a land flora involves two assumptions or surmises:

- (i) One particular type of plant association could not transcend plate boundaries, and
- (ii) More than one plant association could not

thrive on each palaeoplate.

These surmises seem to be natural corollaries of long held belief that the Gondwana Supercontinent had a uniform vegetation all over. The area of the Gondwana Supercontinent comprising all the continents of the Southern Hemisphere and India should total to some millions of square kilometres, with a south-north extent from the South Polar Region to Tropic of Cancer atleast. If the accretion of Turkey, Afghanistan, Tarim Basin, etc. as a part of the Indian Plate is also accepted, the northern margin of this plate may well have reached the Permian equator. It seems improbable that such a huge landmass had a uniform vegetation cover, a vegetation that did not show any provincialism even at micro-level. One would rather expect some degree of provincialism in floral composition in an area, much smaller than that covered by Gondwanan India.

The distribution of the vegetation undoubtedly is an active attribute of land-sea distribution, and climatic thermometry, i.e., palaeolatitudes. It does not seem plausible that each taxon of land plants could have thrived simultaneously both in cool-temperate and subtropical-tropical areas and that each taxon would have populated the Gondwana Supercontinent all over, at the same time.

The concept of the so-called mixed floras seems to have complicated our understanding of the phytogeography of the Permian period. For example, the genus *Glossopteris* established for certain tongue-shaped leaves with reticulate venation and a midrib is the most characteristic element of the Permian flora of Gondwana Supercontinent. In the 1930s similar leaves were recorded in the Angaran Flora. Zimina (1967) reported similar leaves from Permian of Siberia. I have examined these specimens, and had I not known from where these specimens have come, I would have unhesitatingly accepted their placement under the Gondwanan *Gangamopteris* and *Glossopteris*. However, hardly any palaeobiogeographer accepts that these leaves are same as the Gondwanan ones, probably because such an acceptance would not fit in with the concept of Continental Drift. But, reports of *Glossopteris* from Turkey or Indonesia are accepted even though there is no evidence to show that the *Glossopteris*-like leaves from these areas belong to the same lineage as the Gondwanan *Glossopteris* (see Maheshwari & Bajpai, 1988). A leaf from the Jurassic of Oaxaca, Mexico, that has all the morphographical characters of a Gondwanan *Glossopteris* is not accepted as a record of this genus, because the genus is not 'expected' to have continued into the Jurassic. There is a recent view that the genus *Lesleya* from the

Euramerican Flora is the ancestor of *Glossopteris* (Leary, 1991). It all seems to be very subjective thinking which does not allow clear demarcation of macro- or micro-palaeophytogeographical provinces.

It is thus axiomatic that for palaeophytogeographic or palaeoclimatic interpretations for the Gondwana period, one should critically assess systematic and taxonomic position of each taxon of

plant fossils, whether based on a leaf, wood or, pollen. Look-alike plant fossils from disjointed areas do not necessarily mean that they belong to the same plant. For example, the pollen genus *Striatopodocarpites* is known from Euramerican, Angaran, Cathaysian and Gondwanan floras, yet so far we have no evidence to show that any gymnosperm was common to all these floras. Similarly the pollen genus *Potonieisporites* referred to the conifers was originally reported from the Zechstein of Germany (Bharadwaj, 1964), and at the same time it is an important and characteristic constituent of Early Permian floras of the Gondwana Supercontinent. Again we have no evidence if there

was any conifer that was common to Laurasia and Gondwana Supercontinent during Permian. Thus, at macro-level the boundaries between major floristic provinces become blurred due to subjective taxonomic approaches and/or misidentifications.

At the micro-level, for example, during the Gondwana time slice on the Indian subcontinent, the limited spatial distribution of certain elements reflects an incipient to decipherable provincialism. For this one has to consider time slices of reasonable durations only. A phytogeographic reconstruction, say for the Permian Period has no meaning because it would assume that for 40 million odd years there was a uniform distribution of vegetation all over India. Of course, one has also to take into account the fact that a complete sequence of floral succession is yet to be established. As finer stages of Permian are yet to be identified in the Indian Gondwana, a few examples are taken from different formation level units.

Talchir Formation—The formation represents the basal portion of the Indian Gondwana and is usually taken as equivalent of Asselian and Sakmarian stages. The flora of this period was not much diversified and is poorly known. Leaves of the genera *Gangamopteris* and *Pantophyllum* (= *Noeggerathiopsis*) are major components of the flora. No visible provincialism is seen.

Barakar Formation—The Barakar Formation conformably succeeds the Talchir Formation and is equivalent of Artinskian Stage. Some authors classify the lower part of the formation as an independent formation—the Karharbari. This unit does have a distinct floral association and hence here it is considered as a biozone.

The Karharbari biozone is reported from a number of coalfields (Table 3). The common elements of the flora are leaves of the genera *Pantophyllum* (= *Noeggerathiopsis*), *Gangamopteris* and *Glossopteris*. The biozone is best developed in the Giridih Coalfield, where the characteristic elements are *Botrychiopsis*, *Rubidgea* and *Buriadia*. The first two genera have not been found so far from any other place in India. *Botrychiopsis* is known from Australia and Argentina, and *Rubidgea* from South Africa. The synchronicity of these records with the Giridih record is yet to be established. The genus *Buriadia* is known from the Pali and Ib-River coalfields, as also from the Raniganj Formation of Raniganj Coalfield. The latter record is doubtful. Thus for the Karharbari time slice, the flora of Giridih Coalfield does show a decipherable provincialism.

In the Barakar Formation *sensu stricto*, the genera *Pantophyllum* (= *Noeggerathiopsis*) and *Gangamopteris* became almost extinct; the former genus has recently been recorded from the lower

are apparent, though not necessarily of the same age (Map 1). These provinces are:

- (i) Perigondwana (Mamal Formation), with *Lobatannularia*, *Sphenophyllum*, *Rajabia* (= *Pecopteris*) and *Kashmiropteris*. All these genera are important constituents of the Cathaysian Flora, and except for the genus *Sphenophyllum* are not known from the Gondwanan flora.
- (ii) Northern Rajmahal Basin (Hura Coalfield), with *Sphenophyllum* (dimorphic leaves), *Dactylophyllum digitata*-type, *Saportaea*, *Psymophyllum*, *Rhipidopsis*, *Ginkgoites*, *Veekeysinghia*, *Birbalsabnia*, etc. Leaves resembling those of the genus *Saportaea* have recently been discovered in the fireclays of Auranga Coalfield. The genus is also known

from Permian of China and United States of America. On the Gondwana Supercontinent, it has been reported from the Triassic of South Africa (Anderson & Anderson, 1989). *Dactylophyllum digitata* is known only from the Late Carboniferous of Australia (Morris, 1975). A *Potonieisporites-Hamiapollenites* palynological association has also been recorded from the Hura Coalfield. These two genera normally are not expected to occur

together; in India, *Potonieisporites* is confined to Early Permian, and *Hamiapollenites* to Late Permian.

(iii) Main Gondwana country, including Damodar, Son-Mahanadi and Pranhita-Godavari grabens, and probably also eastern Himalaya. The genera *Barakaria* and *Diphylopteris* are endemic to the Auranga Coalfield. The only other known record of the genus *Barakaria* is from the Angaran flora (Meyen, 1969).

Raniganj Formation—The flora of the Raniganj and 'equivalent' formations (Table 6-11) is relatively more diversified. Here, too, an incipient provincialism is decipherable. The flora of this formation in the Raniganj Coalfield, where it is best known, has a characteristic element, *Palaeovittaria*, which is not known from any other equivalent bed. The genus has recently been reported from the Barakar Formation of Raniganj Coalfield (Srivastava, 1992), and the Mamal Formation of the Perigondwana (Pant *et al.*, 1991). Alongwith certain other genera, such as, *Belemnopteris*, *Rhabdotaenia*, the flora of Damodar Graben has a decipherable compositional difference as compared to equivalent floras from other areas. For example, the Hinjir Formation of the Mahanadi Valley has yielded fossils referable to the family Eretmoniaceae (Maheshwari, 1990), which are restricted to this area. The fossils of this family are known only from Queensland in

Australia and Natal in South Africa. The upper part of the Pali Formation (Nidhpuri Plant beds) in the Son Graben also contains certain endemic elements, such as the genera *Nidia*, *Nidistrobus*, *Satsangia*, etc. The beds also contain 'Thinnfeldia' callipteroides-type of leaves, which in literature have been named as species of the genus *Dicroidium*. The genus *Lelstotheca* is restricted to the Pachwara Formation of Pachwara Coalfield, though it possibly occurs in the Barakar Formation of Hura Coalfield also.

The few examples discussed above reveal that at certain points of time some of the plant taxa had a restricted geographical distribution, and on the basis of such occurrences few incipient or apparent micro-palaeophytogeographical provinces can be delineated. However, much more work needs to be carried out as most of the regions are underexplored, and a complete sequence of floral succession is yet to be established for all the Gondwanan areas.
